ARTIFICIAL INTELLIGENCE AND VIRTUAL ENVIRONMENT APPLICATION FOR MATERIALS DESIGN METHODOLOGY

The purpose of this study is to develop a methodology for material design. This methodology will enable the selection of production descriptors to ensure the required mechanical properties of structural steels specified by the designer of machinery and equipment. The selection is performed by using a computational model developed with use of artificial intelligence methods and virtual environment. The model is designed to provide impact examinations of these factors on the mechanical properties of steel only in the computing environment. Virtual computing environment allows full usage of the developed intelligent model of non-alloy and alloy structural steel properties and provides an easy, intuitive and user-friendly way to designate these properties for products after heat and plastic treatment. Also, very easy is the determination of chemical composition, treatment conditions and geometric dimensions on the basis of the steels mechanical properties. The proposed solutions allow the usage of developed virtual environment as a new medium in both, the scientific work performed remotely, as well as in education during classes. It is also possible the extension of this model to other groups of materials, not just for steel.

1. INTRODUCTION

The increasing consumer demands about better quality of steel products are forcing on manufacturers the usage of more precise manufacturing processes, which are based on the rigorous standards. To stay on the market, it is necessary to use computer systems supporting steel production or project managing on each stage of manufacturing. Increase in computing power, observed in recent years, favours the development of modern tools used for improving of product quality or for lowering its price. On special attention deserves, developed for several years, computer systems based on artificial intelligence methods and used to predict the mechanical properties of manufactured material. These systems absolving manufacturers from the multiple repetitions of expensive and long-term laboratory researches. The ability of structural steels mechanical properties obtainment is extremely valuable for manufacturers and designers, which are manufacturing or using steel elements. This allows fulfilling all customers' requirements regarding the quality of supplied products. Modelling of steels mechanical properties is also associated with financial benefits, when expensive and time-

¹ Institute of Engineering Materials and Biomaterials, Silesian University of Technology, ul. Konarskiego 18a, 44-100 Gliwice

consuming researches are reduced to necessary minimum. Necessary to conduct is only the verification of computations [1-4].

This situation forced to develop a new computational model covering a wide range of input values, such as the high number of chemical elements, treatment conditions and geometrical dimensions, and relate them with the greatest possible number of mechanical properties. Suitable tools developed for modelling facilitation of these properties will enable more effective selection of steel production descriptors. It will also enable manufacturing of higher quality product, which are cheaper and are more optimized for customer needs. The development of computational methods and computer simulations resulted in replacement of the traditional laboratory in favour of the virtual laboratory. Development of virtual tools, which are simulating the investigative equipment and simulating the research methodology, can serve as a basis for combining aspects of laboratory research, simulation, measurement, and education. Application of these tools will allow the transfer of research and teaching procedures from real laboratory to virtual environment. This will increase the number of experiments conducted in virtual environment and thus, it will increase the efficiency of such researches. This will also allows the training of more professionals. This is not the work on real hardware. This is work with use of suitably designed simulators, namely those, in which the real research methodology is faithfully reproduces. Such simulators are very helpful, not only in industrial applications, but also in engineering education. Such researches were already preformed in the Department of Materials Processing Technology, Management and Information Technology in Materials Institute of Engineering Materials and Biomaterials, but this was not an integrated and comprehensive approach. Presented in this paper the new approach allows the methodical use of all available computational techniques, including the artificial intelligence tools and virtual environment [4-6].

2. LITERATURE REVIEW

The aim of new engineering materials design is to optimize their functional properties in technological, economic and environmental aspect. This usually applies to products made from these materials, which meet the strict usage requirements. Such design, usually computer aided, must be based on a thorough knowledge of relations (theoretical and empirical) between the chemical composition of the material, its structure, treatment conditions and mechanical properties. The main benefit is the ability to design a suitable material selection (or manufacturing) methodology for various industrial applications [7-9].

Models shall be construed as a reflection of the system with use of logical relationships between variables describing them. Manipulation of these variables allows the analysis, how the model behaves in certain conditions [10]. Computational model is a simplified description of the relation between steels mechanical properties and conditions of its production (Fig. 1.). It ignores certain dependencies occurring in reality (considered by model developers to be less important) [8],[11-13].

Evaluation of simulation results obtained with use of developed computational model is based on comparison of all relevant variables model with the measured data [14-15]. It is recommended when developing a model to obtain a comparable level of the representation accuracy for most variables than the unusually precise terms of one variable (although important), and poorly to others [16-19].

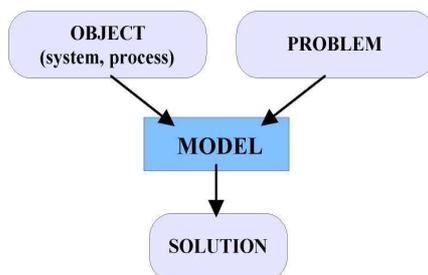

Fig. 1. The idea of modelling

Computational material models are collections of information on their properties and descriptors, expressed as a mathematical equation. Modelling is thus formalizing the description methodology of the given property, limited to set of properties shown by the physical model with use of formulas and mathematical relationships. This means that the physical model determines the form of a mathematical model. The mathematical model should clearly correspond to the physical model. There are many techniques of mathematical modelling using several different algorithms described in available literature. They are used among others to modelling the steels mechanical properties. Equally large is collection of articles and books related to properties' modelling, from the simple dependence equations, through statistical analyses and on the methods of artificial intelligence finishing. However, there is no universal method of mechanical properties prediction. Developed and described in the literature models can be applied in very limited range of the chemical elements concentration or even for single steel grade with very narrow manufacturing conditions. Some part of all models does not take into consideration important conditions as e.g. the production focusing exclusively on the chemical composition on maximum four alloy additions [20-23].

Virtual laboratory is, located in virtual environment, set of simulators and trainers, whose main objective is to simulate the research methodology of investigative equipment located in real scientific laboratory. Additionally, user can find manual instructions of equipment usage, real and virtual experiments descriptions, training exercises possible to perform and many other materials supporting the cognitive processes of research methodology. Virtual laboratory is among other, training environment for staff and students who have just started work with the given device type. They can acquire basic skills and abilities to operate the device without worrying about damaging expensive equipment or causing danger to life or health of their own and other peoples present in the lab. Improper handling of simulated device ends only on the simulated malfunction or damages, visible only on the monitor screen. Then, user simply needs to reset the simulation to the initial state and repeat the experiment with the introduced correct parameters. Researches conducted in

academic centres indicate, that the ability to perform the experiment at home without supervisor has a positive effect on the student. He don't feel helpless and he doesn't make as many mistakes as a student familiar only with the theoretical descriptions of machines and having a first contact with the real device only in the classroom under the supervision of an instructor leading the subject [24-34].

3. COURSE AND SCOPE OF OWN WORK

In order to develop a computer-aided method of steel mechanical properties modelling with use of artificial intelligence tools and virtual environment materials research were carried out in order to build a database of experimental results. These results were then used in the training process of artificial neural networks. This database was used to build a computational dependences model based on structural steels. To take full advantage of the developed computational model a materials science virtual laboratory was designed, developed and then used to predict the mechanical properties of the structural steels and to visualization of modelling results. It is placed in virtual reality an open science, research, simulation and teaching environment, which enable researches on selected mechanical properties of structural steels. Verification researches were performed to confirm the efficiency of virtual environment application for the purpose of modelling, simulation and prediction of mechanical properties of engineering materials on the example of structural steel. Developed software and obtained experimental results were used to work on the modelling of production conditions of steel meeting the requirements specified by the designers of machinery and equipment. Possible are also classes on science research methodology and operation of research equipment for students and young engineers carried out by use of traditional and e-learning methods.

Non-alloyed and alloyed structural steels were selected for examinations as example material. As the main criterion for selection of steel types was the carbon concentration, which for structural steel does not exceed 0.6% [35-36]. Further criteria for minimal and maximal chemical elements concentration, conditions of heat and plastic treatment were taken from [49] and [50]. The selection of mechanical properties, which were examined was based on [51] and on analysis of the steel markets [41-45] and study the literature [7],[12],[37-40].

For the description of structural steel, six mechanical properties present in the metallurgical certificate have been selected. To describe the above properties set of descriptors characterizing steel in manufacturing process has been developed. It consists of chemical composition described by concentration of thirteen of the most common elements in steels, two technologies of heat treatment used in manufacturing, two technologies of plastic treatment and the geometric dimensions of the final product. Steel was manufactured in electric arc furnaces with devices for steel vacuum degassing (VAD). The material was supplied in the form of heat and plastic treated long rods.

Developed artificial neural networks were used to build the computational dependency model in structural steel. To build such model forty-nine artificial neural networks were trained. This model was built to verify the correctness of networks' training process and to enable the effective usage of artificial neural networks for prediction and modelling

of structural steels properties. The model describes the relationships, which exist between the conditions of steel production and its mechanical properties after manufacturing. After passing into models' inputs the input parameters, which are:

- in case of straight modelling - chemical composition, heat and plastic treatment conditions and geometrical dimensions,
- in case of reversed modelling - mechanical properties.

These values are transferred into active block in the computation model. There, these values are distributed simultaneously on all artificial neural networks. Complete results, namely:

- in case of straight modelling - values or ranges of materials properties,
- in case of reversed modelling - concentrations of chemical elements, conditions of heat and plastic treatment or geometric dimensions,

are transferred outside of the model through the user interface. This model was, in the next step, used to build a materials science virtual laboratory. In application part of the laboratory, developed model is used in direct determination of the descriptors or properties of examined steels. In the network part on the basis of achieved results, the virtual sample file is generated. This file is a representation of real material sample in virtual environment. To obtain the results from this file it should be examined with the use of investigative equipment simulators, like a real material sample.

In order of experimental verification of the developed computational dependency model, a dozen types of non-alloy and alloy structural steels for different purposes were selected for examinations. Comparative studies were conducted using the material science virtual laboratory and real laboratory of the Institute of Engineering Materials And Biomaterials. A set of files describing the conditions of production and mechanical properties of selected species and corresponding to them real, material samples taken from the ready-made steel rods were developed. At model inputs, the production conditions of steel were inputted. Obtained computational results were compared with those obtained by real examinations of real samples of steel material. The results obtained during examination of real steel were introduced into the material science virtual laboratory. Results obtained in virtual environment were compared with results obtained in real investigations. Computations were conducted independently for all tested steel types. Based on the simulation data, graphs showing the impact of the steel descriptor on the selected mechanical property of steel was developed. In the appropriate panel of NeuroLab application, production conditions among with the steels property with an appropriate range of variability were inputted. Operations performed in order to design new type of steel were made. Designed new steel should fulfil all strict requirements given by the customer in terms of production conditions and mechanical properties. New steel types were developed with use of material science virtual laboratory as material sample files, which are describing new types of steel meeting all requirements in virtual environment. In order to verify the correctness of performed simulations new steel types were manufactured in real world. The results obtained by modelling and simulation were compared with results obtained experimentally. Materials descriptors and mechanical properties values, which were used in the verification of the model in design of new steel types and in the researches of mechanical properties of structural steels, were produced by another production company. This data wasn't used at any stage in the process of building the model.

4. ANALYSIS OF OWN WORK RESULTS

Accepted ranges of investigated steels chemical elements are shown graphically in (Fig. 2a). Ranges of heat and plastic treatment conditions of examined structural steels are presented on chart (Fig. 2b) for quenched and tempered steel and on (Fig. 2c) for normalised steel. Materials researches have been partially realised in the laboratories of the Institute of Engineering Materials and Biomaterials, and partly in a research laboratories "Batory" in Chorzów, Poland [46]. Results of investigations are shown on Fig. 3. In order to build the

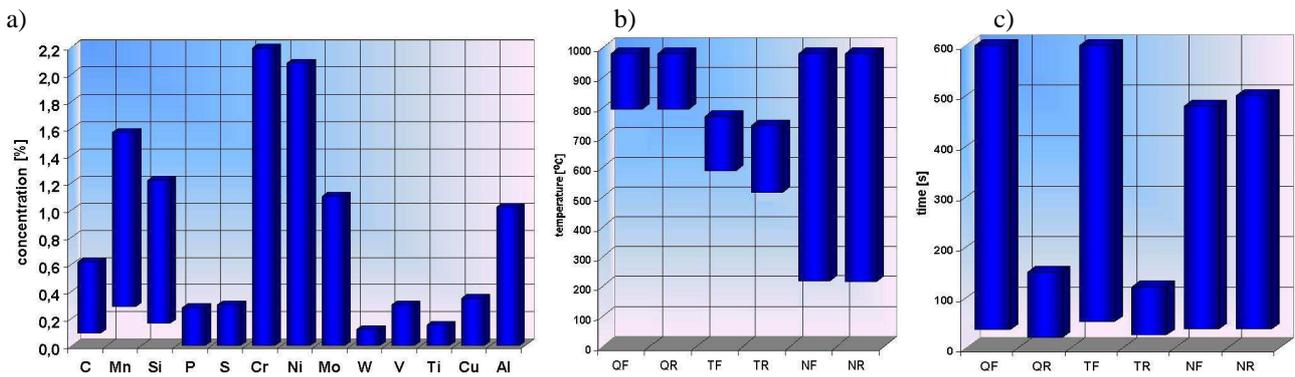

Fig. 2. Ranges of a) chemical elements concentration, b) temperature of heat treatment, c) time of heat treatment in investigated structural steels

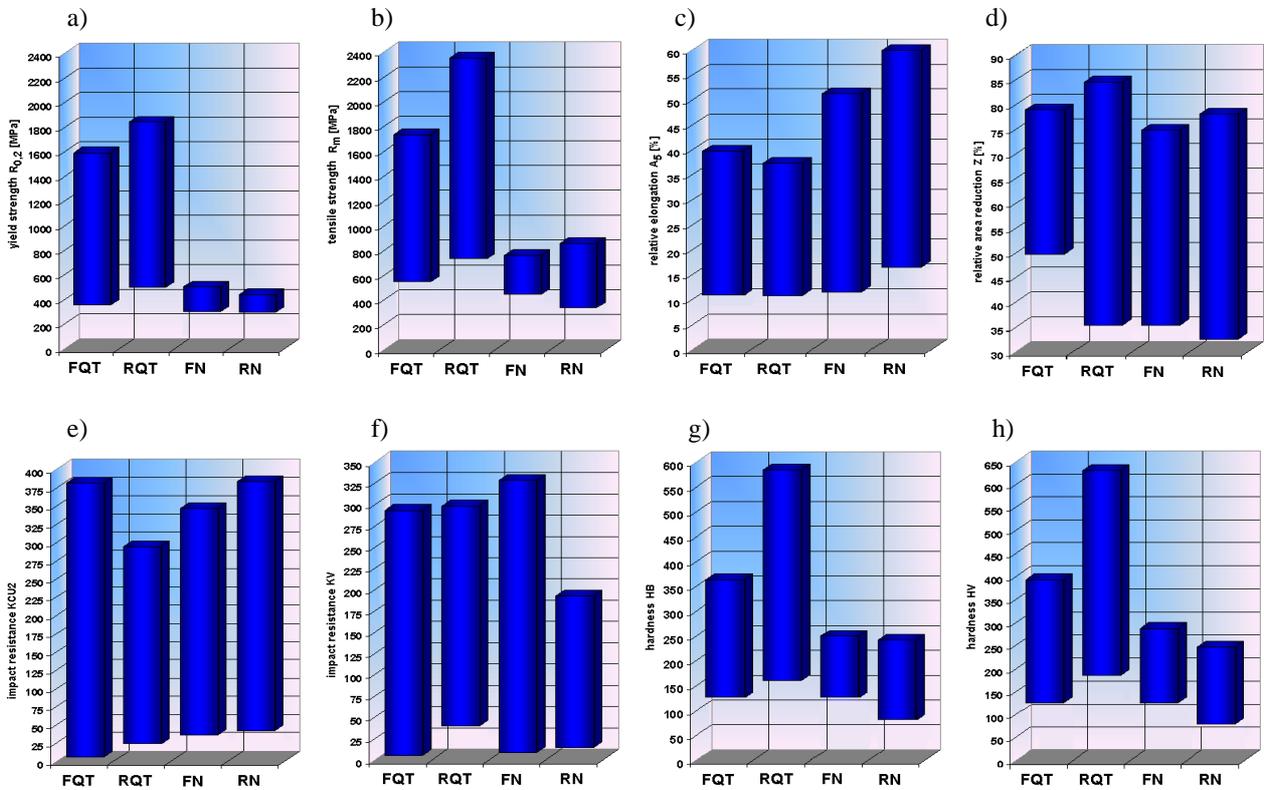

Fig. 3. The ranges of obtained test results a) yield strength $R_{0.2}$, b) tensile strength R_m , c) relative elongation A_5 , d) relative area reduction Z, e) impact strength (KV), f) impact strength (KCU2) g) Brinell hardness HB, h) Vickers hardness HV

model, set of vectors are divided into four subsets. It was decided, that for each individual property, whose value should be estimated, to create a separate neural networks. For properties whose values in steel certificates are given in a range, two networks were trained to provide the estimation for the minimum and maximum values separately. The best results were obtained with artificial neural networks of multilayer perceptron structure with one or two hidden layers. Network types for each property along with the numbers of neurons and the parameters used in quality assessment for a set of test are shown in tables 1 and 2. In all cases, trained artificial neural network reached a value of the correlation coefficient above 0.9 and the relatively low values of deviation ratio. Architectures of four from all forty-nine trained networks are shown on (Fig. 4).

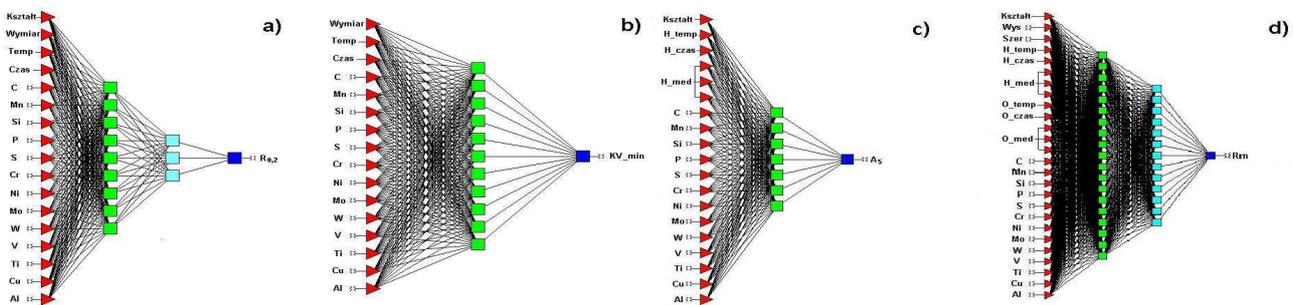

Fig. 4. Types of artificial neural networks used to prediction of mechanical properties a) yield stress of rolled, normalised steel, four-layer perceptron 17:17-9-3-1:1, b) minimal impact resistance of rolled, normalised steel, three-layer perceptron 16:16-11-1:1, c) relative elongation of forged, quenched and tempered steel, three-layer perceptron 17:19-7-1:1, d) tensile stress of forged, quenched and tempered steel, four-layer perceptron 22:26-16-13-1:1

Developed artificial neural networks were the basis for developing a computational model of structural steel dependences. Forty-eight developed artificial neural networks are grouped in four blocks with twelve networks each for steels after normalising, quenching and tempering, rolling and forging. Appropriate block is activated depending on the type of heat and plastic treatment. Each block contains a set of artificial neural networks necessary to carry out the prediction of mechanical properties. A separate network is responsible for steel's type classifications. The examined steel's concentrations of chemical elements are compared with the chemical concentration of base steels and as a result, a base steel type, which the chemical composition is most similar to examined steel's chemical composition, is given.

The training of artificial neural networks itself does not make possible the effective prediction of structural steels mechanical parameters. Statistica Neural Network is superb application for training of such networks. However, it is difficult to apply this system as effective environment applicable for properties modelling. Necessary becomes the creation of new system, which will use of intuitive graphic user interface, will protect the user from processing of incorrect data, will use several neural networks simultaneously, export the modelling results and make accessible the necessary documentation, which will enable the beginning of the work to the user and facilitating her guidance.

To fulfil all requirements a material science virtual laboratory has been developed. It is located in the virtual reality an open, academic, research, simulation and teaching environment, which makes possible researches on selected mechanical properties of structural steels [47-48]. The laboratory was divided into two parts with different functionality. The first part is application "NeuroLab" which use artificial intelligence algorithms to predict the mechanical properties of non-alloy and alloy structural steel. It is an application virtual laboratory, in which on the basis of the input steels manufacturing conditions is possible to determine its mechanical properties without the need for real examinations. Also possible is the reversed inference, namely on the basis of mechanical properties values is possible to determine steel's production conditions.

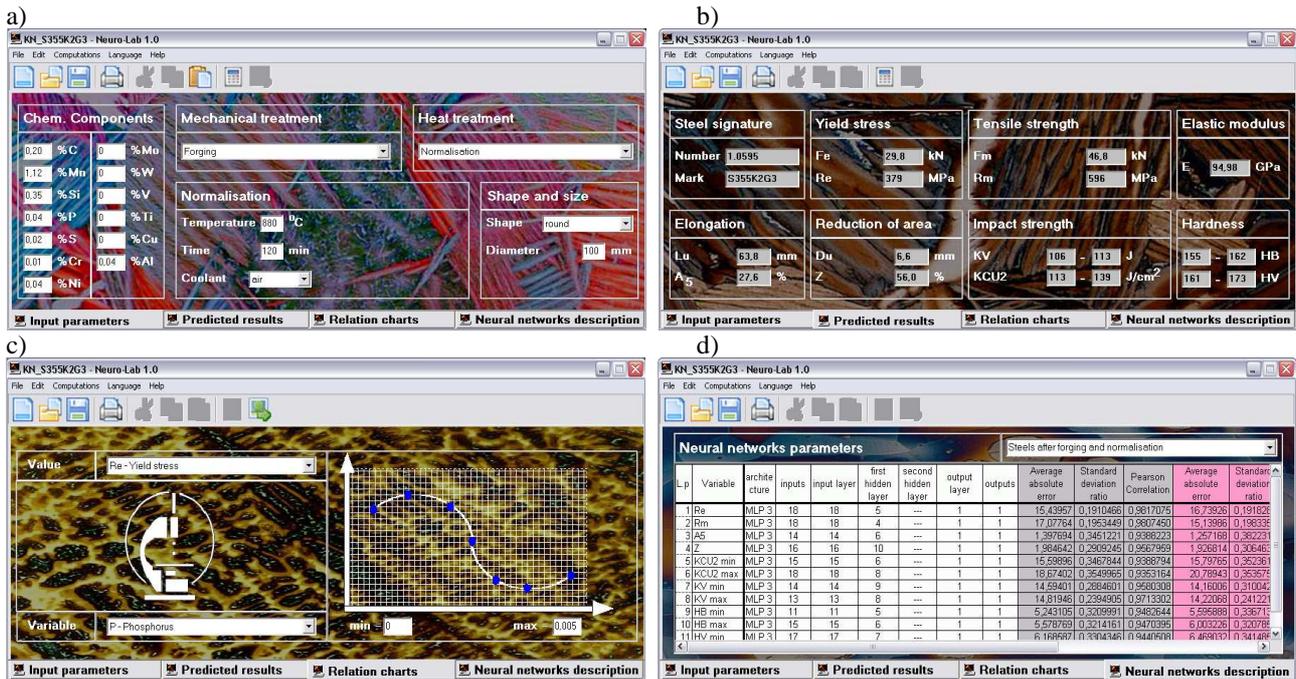

Fig. 5. Application materials science virtual laboratory - NeuroLab 1.0 a) input parameters card, b) predicted results card, c) relation charts card, d) neural networks description card.

The application interface consists of four cards. Input parameters card (Fig. 5a) is used for data input about investigated steel. Predicted results card (Fig. 5b) is used for computation results presentation. Relation chart card (Fig. 5c) is used to generate dependency graphs between the mechanical properties of steel and the production conditions used for their estimation. Neural network description card (Fig. 5d) presents information about the neural networks that were used for the construction of the structural steel dependency model. This model is applied in this software. Results of computational experiments are presented in an open form in the application window or printed as the investigation protocol of the mechanical and technological properties as print the test protocol of mechanical and technological in accordance with [51]. Relations between production conditions and mechanical properties are generated in the form of graphs in a separate window [1-2].

Network part of materials science virtual laboratory is a tool with extended functionality in relation to the NeuroLab application. This is a network laboratory placed in the Internet on e-Learning Platform of the Institute of Engineering Materials and Biomaterials. This same computational model of structural steel's dependencies is applied in network part, so it is possible to perform the same examination range, which can be performed using the application part of virtual laboratory. However, there are differences in examination methodology. Opposite to the application part of the laboratory, in network part user do not receive the results of examinations in the open form. The modelling results are stored in a file, which is a virtual representation of real steel sample in virtual world. In order to obtain the results this file should be placed in machine simulators. Examination of created material model mechanical properties and material structures consists of exact research equipment representation with an exact reproduction of the device's research methodology. Only after the

examination performed in the virtual environment, user gets the property examination result (or an error message when the examination failed because of an error). On (Fig. 6.) examples of the investigative equipment simulations available in the laboratory along with the panel for generating files representing material samples is presented. The research methodology with use of simulations is exactly the same as the real device [1-2].

5. THE VERIFICATION OF EXPERIMENTAL AND VIRTUAL INFLUENCE EXAMINATIONS OF PRODUCTION DESCRIPTORS ON MECHANICAL PROPERTIES OF STRUCTURAL STEELS PERFORMED WITH USE OF MATERIALS SCIENCE VIRTUAL LABORATORY

In order to experimental verification of computational model successively three aspects has been emerged. The first describes the experimental verifications aimed in the correctness verification of the computational model developed in order to answer the question whether it is possible to perform virtual material examinations exclusively in the virtual environment. This was followed by virtual materials researches aimed to determine the influence, which the structural steel's mechanical properties have on steels descriptors, such as the concentration of chemical elements, the conditions of heat and plastic treatment and geometrical dimensions. The last of these activities was to design a chemical composition and heat treatment conditions of two hypothetical structural steels to meet the client's requirements about values of mechanical properties.

For verification purposes, an experimental set of vectors describing the material descriptors and steel's mechanical properties has been developed. These vectors describe each of the 135 types of examined steel. To exclude the possibility of adjusting the artificial neural network only to the products of one manufacturer's material vectors, verification

samples were collected from a different manufacturer. Samples, produced from these types of steel, were examined in order to obtain verification vectors. To minimize differences between training and validation data, material researches has been performed in the same way and using the same equipment, that were used in the main researches. In addition, the vectors used for comparative researches were constructed in the same way as the vectors used for training of artificial neural network used in the calculation model of dependences in to structural steel. Vectors, in which values of material descriptors or mechanical properties went beyond the accepted ranges for the vectors used for construction of artificial neural networks, were rejected. The results obtained by virtual examination have been compared with those obtained experimentally in a real laboratory.

As example, the influence analysis of the admixtures concentration on the mechanical properties is presented. Three types of non-alloy structural steels for general use described in [52] were selected for investigations. Steel signatures and chemical compositions are introduced in Table 3. The material was delivered as forged, normalised round rods with diameter $\Phi 100\text{mm}$. Treatment parameters are: temperature: 880°C , time: 60min, cooling medium: air. Material descriptors were inputted into material science virtual laboratory. The mechanical properties estimation was performed for every single virtual sample. Results obtained with use of this method were compared with results obtained by use of real material investigations. All are introduced in Table 4. It was found, that all estimated results are correct for all examined steel samples, because all three steel species were recognised correctly, and differences among predicted and measured values of mechanical properties are very small and predicted results did not exceed the neural network tolerance values for corresponding property. NeuroLab system has the ability to generate relation graphs between the mechanical properties of steel and parameters used to their estimation. Possible is the examination of the influence of any parameter from the input parameters on the value of any mechanical properties from the predicted results, when the rest of parameters remain unchanged. The next stage of investigative work was the analysis how big is the influence

Table 3. Chemical composition of examined non-alloy steels

of the admixtures concentration on steels mechanical properties. The influence graphs were generated with use of NeuroLab among estimated properties and the concentration of admixtures. The concentration ranges are: Mn to 1.5%, Si to 0.5%, P to 0.05%, S to 0.05%. Influence graphs are presented on Figs. 7-9.

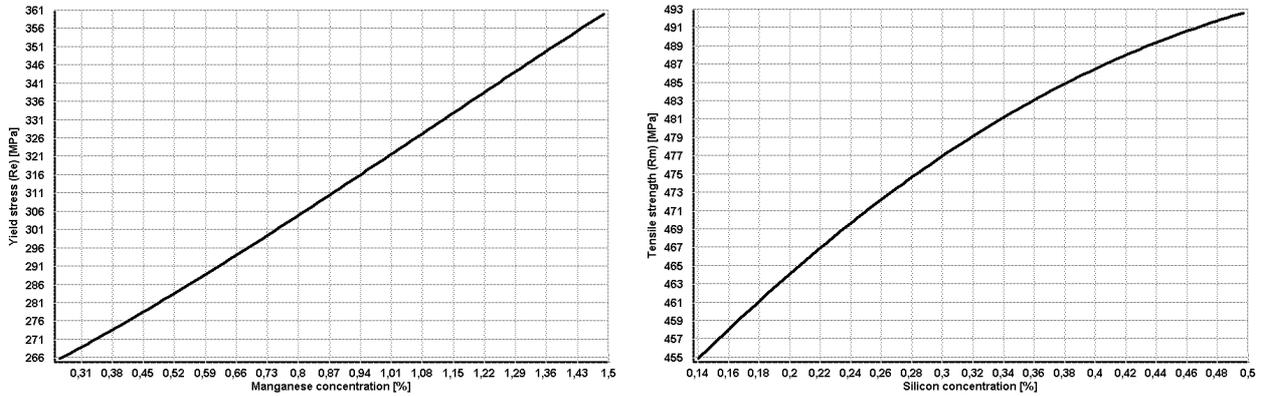

Fig. 7. Influence of manganese and silicon concentration on selected mechanical properties of S235J2G3 steel

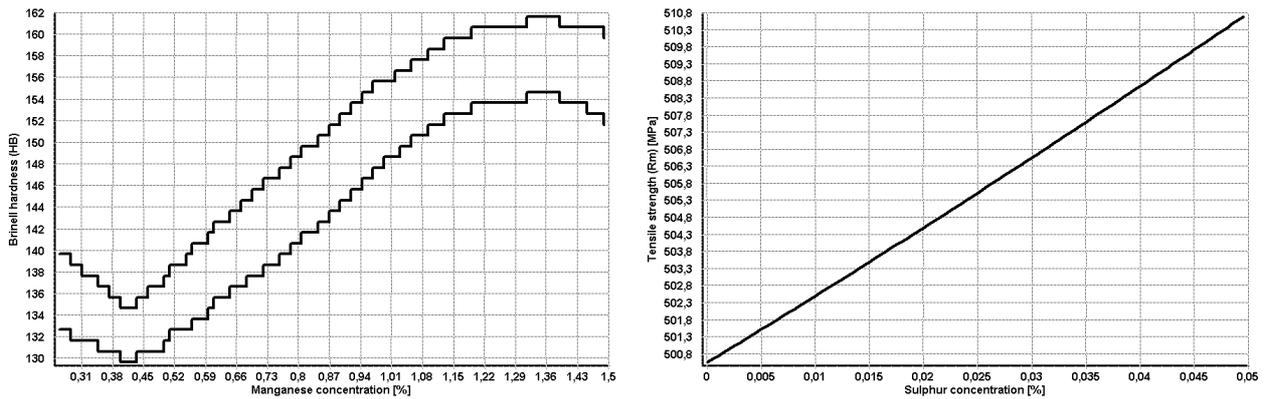

Fig. 8. Influence of manganese and sulphur concentration on selected mechanical properties of S275JR steel

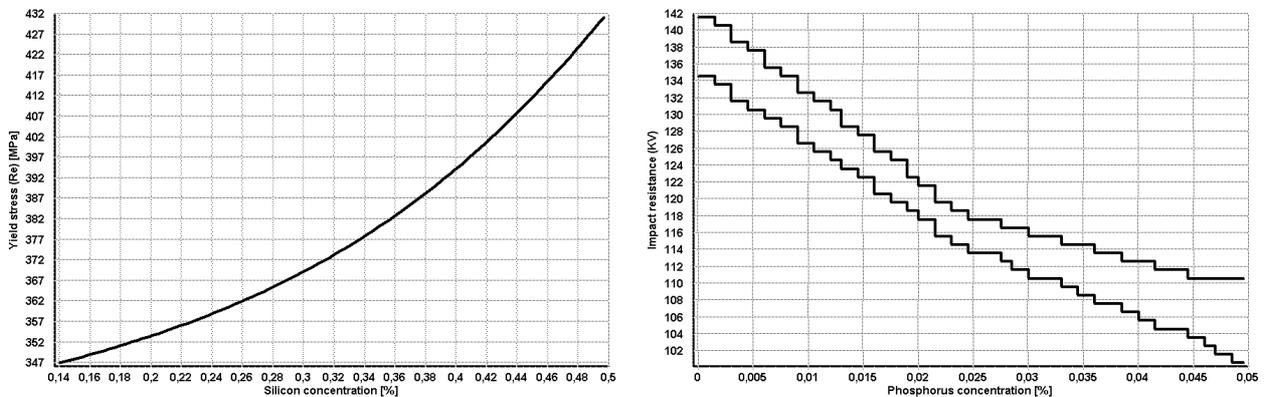

Fig. 9. Influence of silicon and phosphorus concentration on selected mechanical properties of S355K2G3 steel

The first design task for the virtual science virtual laboratory was to design a steel type, which fulfils the strict delivery conditions for concentrations of chemical elements. Demanded by the virtual client steel chemical composition is presented in Table 9. This is the 34CrNiMo6 steel produced in accordance with [53]. Steel has been heat and plastic treated to appropriate size. Processing conditions and geometric dimensions of the product are introduced in Table 5. Virtual client's demand was that steels chemical composition must be adapted to fulfil strictly defined properties with unchanged treatment conditions. For the chemical composition analysis eight chemical elements was selected - carbon, manganese, silicon, chromium, nickel, molybdenum, vanadium and titanium. The second task was to design virtual steel, which meets strict delivery conditions by modifying only the conditions of heat treatment. Chemical composition of base steel supplied by the client (C45R according to [54]) is given in Table 5. Treatment conditions and geometric dimensions of the product are introduced in Table 7. This time, the virtual client's demand was matching of steel's heat treatment condition. Strictly defined properties with unchanged chemical composition should be achieved. All assumptions are summarized in Table 6. Virtual research project in first task consisted in finding such a range of concentrations of given elements, while keeping the other concentrations and treatment conditions unchanged in order to fulfil all conditions for steel properties defined by a virtual client. Virtual research project in the second task included the search for such ranges of temperature and time of quenching and tempering. All conditions for steel properties defined by a virtual client should be fulfilled without changes in the steel's chemical composition.

The results of the analysis are performed in Table 8 for the first task and in Table 10 for the second task. Table 9 shows the results of properties modelling of 34CrNiMo6 steel before

and after the modification of chemical composition, Table 11 shows the results of properties modelling of C45R steel before and after the modification of heat treatment conditions. The relative elongation was not included in examinations, because this condition was already fulfilled the base steel. To verify the operations correctness, steels with revisited descriptors have been manufactured in a factory. Steels from both tasks were marked with symbols PR₁ and PR₂. A modified chemical composition of steel is summarized in Table 12, the modified heat treatment conditions of steel PR₂ are summarized in Table 13. Produced steels after heat and plastic treatment were examined in real laboratory. Obtained results are presented together with the results of the virtual examinations performed with use of material science virtual laboratory in Table 14. Real examinations results are comparable with results of virtual examinations, which means, that the projecting operations were performed correctly.

6. SUMMARY

On the basis of experimental results obtained in the virtual and real examinations of structural steels mechanical properties it has been proved, that the selection of production descriptors of structural steels, can be obtain by using a computational model developed using the artificial intelligence tools and virtual environment. This model is providing the impact study of these factors on the mechanical properties of steel only in computing environment. Results, obtained during virtual experiments, indicates on very good compatibility of the model with the data obtained experimentally in real laboratory. This demonstrate the effectiveness of the model application for the prediction, simulation and modelling of the steel properties and also production descriptors. of newly designed steels.

The model calculation correctness has been fully verified by experiment. Materials researches performed in the virtual environment, both, in range of determining the

mechanical properties and in the field of chemical composition and treatment conditions design, are consistent with the results obtained during the real research in real laboratory. Consistency was observed in the whole range of steel descriptor variation: of concentrations of chemical elements, heat and mechanical treatment conditions and mechanical properties of examined structural steels. Developed virtual environment enables the modelling of new, non-standard types of steel. Through the determination of relations between selected mechanical properties and the steel descriptors at specified range, it is possible to obtain data on the hypothetical and the newly designed materials, which have not been produced yet and existing only in virtual environment. Possibility of designing new materials with unique properties strictly adjusted to actual customer needs is crucial in achieving of the market success. The presented examples of computer aid in structural steel production showing a potential application possibilities of this methodology to support the production of any group of engineering materials.

ACKNOWLEDGEMENT

The authors would like to thank the administration of "Batory" foundry for access to their research results, and to Zeiss Polska for the biological samples, which were helpful in the building of the virtual confocal microscope. The paper has been realised in relation to the project POKL.04.01.01-00-003/09-00 entitled "Opening and development of engineering and PhD studies in the field of nanotechnology and materials science" INFONANO, co-funded by the European Union from financial resources of European Social Fund and headed by Prof. L.A. Dobrzański.
